Pop Quiz!

What is the best workgroup size for …

Gaussian blur, 512px x 512px, floats, on:

1. **AMD HD7990?**
2. **Nvidia GTX Titan?**
3. **Intel i7-3820?**

What is the best workgroup size for …

Gaussian blur, 512px x 512px, floats, on:

1. **AMD HD7990?** 64 x 4
2. **Nvidia GTX Titan?** 96 x 4
3. **Intel i7-3820?** 40 x 24

What is the best workgroup size for …

Nvidia GTX 590, 4096 x 4096 elements running:

1. **Sobel edge detection?**
2. **Heat equation?**
3. **Game of life?**

What is the best workgroup size for …

Nvidia GTX 590, 4096 x 4096 elements running:

1. **Sobel edge detection?** 256 x 2
2. **Heat equation?** 128 x 2
3. **Game of life?** 32 x 6

What is the best workgroup size for …

1. Intel i5-2430, game of life, 4096 x 4096?
2. Nvidia GTX 690, threshold, 512 x 512?
3. Intel i7-3820, NMS, 512 x 512?

What is the best workgroup size for …

1. Intel i5-2430, game of life, 4096 x 4096? 196 x 20
2. Nvidia GTX 690, threshold, 512 x 512? 32 x 4
3. Intel i7-3820, NMS, 512 x 512? 88 x 8

One size does not fit all!

Choosing workgroup size depends on:

1. Device
2. Program
3. Dataset

Autotuning OpenCL Workgroup Size for Stencil Patterns

Chris Cummins Pavlos Petoumenos Michel Steuwer Hugh Leather
University of Edinburgh
c.cummins@ed.ac.uk, ppetoume@inf.ed.ac.uk, michel.steuwer@ed.ac.uk, hleather@inf.ed.ac.uk

Abstract

Selecting an appropriate workgroup size is critical for the performance of OpenCL kernels, and requires knowledge of the underlying hardware, the data being operated on, and the implementation of the kernel. This makes portable performance of OpenCL programs a challenging goal, since simple heuristics and statically chosen values fail to exploit the available performance. To address this, we propose the use of machine learning-enabled autotuning to automatically predict workgroup sizes for stencil patterns on CPUs and multi-GPUs.

We present three methodologies for predicting workgroup sizes. The first, using classifiers to select the optimal workgroup size. The second and third proposed methodologies employ the novel use of regressors for performing classification by predicting the runtime of kernels and the relative performance of different workgroup sizes, respectively. We evaluate the effectiveness of each technique in an empirical study of 429 combinations of architecture, kernel, and dataset, comparing an average of 629 different workgroup sizes for each. We find that autotuning provides a median 3.79× speedup over the best possible fixed workgroup size, achieving 94% of the maximum performance.

1. Introduction

Stencil codes have a variety of computationally demanding uses from fluid dynamics to quantum mechanics. Efficient, tuned stencil implementations are highly sought after, with early work in 2003 by Bolz et al. demonstrating the capability of GPUs for massively parallel stencil operations [1]. Since then, the introduction of the OpenCL standard has introduced greater programmability of heterogeneous devices by providing a vendor-independent layer of abstraction for data parallel programming of CPUs, GPUs, DSPs, and other devices [2]. However, achieving portable performance of OpenCL programs is a hard task — OpenCL kernels are sensitive to properties of the underlying hardware, to the implementation, and even to the *dataset* that is operated upon. This forces developers to laboriously hand tune performance on a case-by-case basis, since simple heuristics fail to exploit the available performance.

In this paper, we demonstrate how machine learning-enabled autotuning can address this issue for one such optimisation parameter of OpenCL programs — that of workgroup size. The 2D optimisation space of OpenCL kernel workgroup sizes is complex and non-linear, making it resistant to analytical modelling. Successfully applying machine learning to such a space requires plentiful training data, the careful selection of features, and an appropriate classification approach. The approaches presented in this paper use features extracted from the architecture and kernel, and training data collected from synthetic benchmarks to predict workgroup sizes for unseen programs.

2. The SkelCL Stencil Pattern

Introduced in [3], SkelCL is an Algorithmic Skeleton library which provides OpenCL implementations of data parallel patterns for heterogeneous parallelism using CPUs and multi-GPUs. Figure 1 shows the components of the SkelCL stencil pattern, which applies a user-provided *customising function* to each element of a 2D matrix. The value of each element is updated based on its current value and the value of one or more neighbouring elements, called the *border region*. The border region describes a rectangular region about each cell, and is defined in terms of the number of cells in the border region to the north, east, south, and west of each cell. Where elements of a border region fall outside of the matrix bounds, values are substituted from either a predefined padding value, or the value of the nearest cell within the matrix, determined by the user.

When a SkelCL stencil pattern is executed, each of the matrix elements are mapped to OpenCL work-items; and this collection of work-items is divided into *workgroups* for execution on the target hardware. A work-item reads the value of its corresponding matrix element and the surrounding elements defined by the border region. Since the border regions of neighbouring elements overlap, each element in the matrix is read multiple times. Because of this, a *tile* of elements of the size of the workgroup and the perimeter border region is allocated as a contiguous block in local memory. This greatly reduces the latency of repeated memory accesses
